Lecture I-V summary

Knudsen number: $K_n =$ Mean free path / smallest length scale

<u>Shallow water equations</u>: Assumption $H \ll L$ and homogeneous (*ρ=const.*)
1) Use scaling to obtain hydrostatic equilibrium and incompressibility
2) Obtain $\nabla_H p = \rho g \nabla_H \eta$
3) Use continuity and BC to obtain $\dfrac{Dh}{Dt} + h \nabla_{H \cdot u} = 0$

<u>Two layer model</u>: Assumption same as before, note $\nabla_H p_0 = 0$.
1) Write NS equations with new continuity.
2) First layer same as before
3) The second layer uses continuous pressure. $p_2(z) = p_0 + \rho_1 g (\eta 0 - \eta 1) + \rho_2 g (\eta_1 - z)$
4) Obtain reduced gravity $g' = g \dfrac{\rho_2 - \rho_1}{\rho_1}$

<u>Reduced gravity model</u>: (aka 1.5) Assumption $H_2 >> H_1$.
1) Notice that shallow part is much faster, $u_2 \approx 0$
2) Obtain relation $\nabla_H \eta_0 \approx - \dfrac{g'}{g \nabla_H \eta_1}$
3) Set $h_1 = \eta_0 - \eta_1$ which gives g' and h_1 for upper layer

<u>Potential vorticity</u>: Material invariance, assume shallow. Use $\zeta = \left(\dfrac{\partial v}{\partial x} - \dfrac{\partial u}{\partial y} \right)$.

Note: All functions of Q are material invariants.

<u>Linear wave solution</u>: Assume SWE, $f = f_0$ and $u = \varepsilon u'$, $v = \varepsilon v'$, $\eta = H + \varepsilon \eta'$.
1) Neglect all ε^2 terms.
2) Apply Fouriers ansatz
3) Solve for $\omega(f, k, l)$
4) Two solutions:
    a) $\omega = 0 \rightarrow$ Geostrophic
    b) $\omega \neq 0 \rightarrow$ Pointcarté waves
5) Use $c = \sqrt{gH}$ and Rossby number of deformation $L_D = \dfrac{c}{f_0} = \dfrac{\sqrt{gH}}{f_0}$.
    a) If SW: $\omega \gg f_0 \rightarrow \omega^2 = c^2(k^2 + l^2)$
    b) if LW: $\omega \approx f_0$ "Internal oscillations"

<u>Geostrophic adjustment</u>: Assume linearized waves
1) Use equations to derive expression for $\zeta(Q)$
2) Begin by doing $\dfrac{\partial(eq\,1)}{\partial x} + \dfrac{\partial(eq\,2)}{\partial y} = - g \nabla H^2 \eta$
    a) Insert ζ when possible
    b) Use continuity as $\dfrac{\partial^2 \eta}{\partial t^2} = - H \dfrac{\partial \eta}{\partial t} \left[\dfrac{\partial u}{\partial x} + \dfrac{\partial v}{\partial x} \right]$
3) Split solution into homogeneous and particular as $\eta = \eta_w(t) + \eta_p$
4) Use the starting scenario to determine Q, use relation from before.
5) Use particular solution to derive η_p and determine geostrophic wind.
